

**Question 3**
**MAGNETOHYDRODYNAMIC (MHD) GENERATOR**

A horizontal rectangular plastic pipe of width  $w$  and height  $h$ , which closes upon itself, is filled with mercury of resistivity  $\rho$ . An overpressure  $P$  is produced by a turbine which drives this fluid with a constant speed  $v_0$ . The two opposite vertical walls of a section of the pipe with length  $L$  are made of copper.

The motion of a real fluid is very complex. To simplify the situation we assume the following:

- Although the fluid is viscous, its speed is uniform over the entire cross section.
- The speed of the fluid is always proportional to the net external force acting upon it.
- The fluid is incompressible.

These walls are electrically shorted externally and a uniform, magnetic field  $\mathbf{B}$  is applied vertically upward only in this section. The set up is illustrated in the figure above, with the unit vectors  $\hat{x}$ ,  $\hat{y}$ ,  $\hat{z}$  to be used in the solution.

- Find the force acting on the fluid due to the magnetic field (in terms of  $L$ ,  $B$ ,  $h$ ,  $w$ ,  $\rho$  and the new velocity  $v$ ) [2.0 pts]
- Derive an expression for the new speed  $v$  of the fluid (in terms of  $v_0$ ,  $P$ ,  $L$ ,  $B$  and  $\rho$ ) after the magnetic field is applied. [3.0 pts]
- Derive an expression for the additional power that must be supplied by the turbine to increase the speed to its original value  $v_0$ . Copy your result onto the **answer form**. [2.0 pts]
- Now the magnetic field is turned off and mercury is replaced by water flowing with speed  $v_0$ . An electromagnetic wave with a single frequency is sent along the section with length  $L$  in the direction of the flow. The refractive index of water is  $n$ , and  $v_0 \ll c$ . Derive an expression for the contribution of the fluid's motion to the phase difference between the waves entering and leaving section  $L$ . Copy your result onto the **answer form**. [3.0 pts]
